EFFICIENT PRECONDITIONERS FOR PDE-CONSTRAINED OPTIMIZATION PROBLEM WITH A MULTILEVEL SEQUENTIALLY SEMISEPARABLE MATRIX STRUCTURE*

YUE QIU†, MARTIN B. VAN GIJZEN‡, JAN-WILLEM VAN WINGERDEN†, MICHEL VERHAEGEN†, AND CORNELIS VUIK‡

Abstract. PDE-constrained optimization problems yield a linear saddle-point system that has to be solved. We propose a preconditioner that makes use of the global MSSS structure and a preconditioner that exploits the block MSSS structure of the saddle-point system. For the computation of preconditioners based on MSSS matrix computations, model order reduction algorithms are essential to obtain a low computational complexity. We study two different model order reduction approaches, one is the new approximate balanced truncation with low-rank approximated Gramians for SSS matrices and the other is the standard Hankel blocks approximation algorithm. We test our preconditioners on the problems of optimal control of the convection-diffusion equation in 2D and of the Poisson equation in 3D. For 2D problems, numerical experiments illustrate that both preconditioners have linear computational complexity and the global MSSS preconditioner reduces the number of iterations significantly and needs less computation time. Moreover, the approximate balanced truncation algorithm is computationally cheaper than the Hankel blocks approximation algorithm. Besides the mesh size independent convergence, the global MSSS preconditioner also gives the regularization parameter independent convergence, while the block MSSS preconditioner just gives mesh size independent convergence. For 3D problems, both the block MSSS preconditioner and global MSSS preconditioner give virtually mesh size independent convergence. Furthermore, the global MSSS preonconditioner reduces the number of iterations dramatically compared with the block MSSS preconditioner.

Key words. PDE-constrained optimization, saddle-point problem, preconditioners, multilevel sequentially semiseparable matrix, model order reduction, low-rank approximation

1. Introduction.

PDE-constrained optimization problems have a wide application such as optimal flow control [6, 7], diffuse optical tomography [1], and linear (nonlinear) model predictive control [5]. The solution of these problems is obtained by solving a large-scale linear system of saddle-point type. Much effort has been dedicated to finding efficient iterative solution methods for such systems. Some of the most popular techniques are the conjugate gradient (`CG`) [21], minimal residual (`MINRES`) [27], generalized minimal residual (`GMRES`) and induced dimension reduction (`IDR(s)`) [38] methods. Their performance highly depends on the choice of preconditioners. In this paper, we study a class of preconditioners that exploit the multilevel sequentially semiseparable (MSSS) structure of the blocks of the saddle-point system.

Semiseparable matrices appear in many applications, e.g., integral equations [23], Gauss-Markov processes [25], boundary value problems [24], rational interpolation [39] and Kalman filtering [29]. Semiseparable matrices are matrices of which all the sub-matrices taken from the lower-triangular or the upper-triangular part are of rank at most 1, as defined in [42]. Sequentially semiseparable (SSS) matrices of which the off-diagonal blocks are of low-rank, not limited to 1, introduced by Dewilde et al. in [12] generalize the semiseparable matrices. Multilevel sequentially semiseparable matrices generalize the sequentially semiseparable matrices to the multi-dimensional cases. Systems that arise from the discretization of 1D partial differential equations typically have an SSS structure. Discretization of higher dimensional (2D

or 3D) partial differential equations gives rise to matrices that have an MSSS structure [15, 22]. Under the multilevel paradigm, generators that are used to represent a matrix of a higher hierarchy are themselves multilevel sequentially semiseparable of a lower hierarchy. The usual one-level sequentially semiseparable matrix is the one of the lowest hierarchy. Operations like matrix inversion and matrix-matrix multiplication are closed under this structure. The LU factorization can also be performed in a structure preserving way. This factorization results in a growth of the rank of the off-diagonal blocks. Consequently, the LU factorization is not of linear computational complexity. Model order reduction can be used to reduce the rank of the off-diagonal blocks, which yields an inexact LU decomposition of an MSSS matrix that can be used as a preconditioner.

In [22], Gondzio et al. first introduced the MSSS matrix computations for preconditioning of PDE-constrained optimization problems. They exploited the MSSS matrix structure of the blocks of the saddle-point system and performed an LU factorization for MSSS matrices to approximate the Schur complement of the saddle-point system. With this approximated Schur complement as a preconditioner, conjugate gradient iterations were performed to solve the saddle-point system block-by-block. As aforementioned, the model order reduction plays a vital role in obtaining a linear computational complexity of the LU factorization for MSSS matrices. In [22], Gondzio et al. used a standard model order reduction algorithm [12, 19] to reduce the computational complexity.

This paper extends [22] in the following ways: 1) We propose a new model order reduction algorithm for SSS matrix computations based on the correspondence between linear time-varying (LTV) systems and blocks of SSS matrices. This new model order reduction algorithm is motivated by the work in [9, 11]. In [9], the approximate balanced truncation was addressed for the model order reduction of linear time invariant (LTI) systems, while in [11] the recursive low-rank approximation was performed to compute the approximation of the Gramians of LTV systems. In this paper, we use the low-rank approximation method in [11] and the approximate balanced truncation in [9] for the model order reduction for the SSS matrices. Compared with the model order reduction algorithms discussed in [12, 19], the approximate balanced truncation method for SSS matrices in this paper is computationally cheaper. 2) With these model order reduction algorithms, we can compute an inexact LU factorization for the MSSS matrix blocks of the saddle-point system in linear computational complexity ($\mathcal{O}(N)$). This yields a block preconditioner for the saddle-point systems. Exploiting the block structure of the saddle-point system is a standard preconditioning technique, which is described in [4]. However, only the single preconditioner for the last block of the saddle-point system is studied in [22]. 3) By permuting the blocks of the saddle-point system, we can also compute an inexact LU factorization of the global system with MSSS matrix computations in linear computational complexity. This gives a global MSSS preconditioner and this novel MSSS preconditioner gives mesh size and regularization parameter independent convergence. This is a big advantage over the block MSSS preconditioner. 4) Besides the problem of optimal control of the Poisson equation, we also study the problem of optimal control of the convection-diffusion equation. 5) Moreover, we extend these preconditioning techniques to 3D saddle-point systems.

Note that the convergence of using block preconditioners depends on the regularization parameter β for the PDE-constrained optimization problems [32]. For small β, block preconditioners do not give satisfactory performance. Since all the blocks of the saddle-point matrix are MSSS matrices, we can permute the saddle-point matrix into a single MSSS matrix. Then we can compute an approximate LU factorization for the permuted saddle-point system using MSSS matrix computations in linear computational complexity. We call this approximate factorization for the permuted global matrix the global MSSS preconditioner. Block preconditioners often neglect the regularization term $\frac{1}{2\beta}M$, and as a result give poor

ETNA
Kent State University
http://etna.math.kent.edu

convergence for small enough regularization parameter β. Our Global MSSS preconditioner does not neglect the regularization term, which in turn gives β independent convergence as well as mesh size independent convergence. Numerical experiments in this paper demonstrate such performance.

The outline of this manuscript is as follows: Section 2 formulates a distributed optimal control problem constrained by PDEs. This problem yields a linear saddle-point system. In Section 3, we give some definitions and algorithms for MSSS matrices to introduce the MSSS preconditioning technique. The new model order reduction algorithm for SSS matrices is also described. With MSSS matrix computations, we propose two types of preconditioners for saddle-point problem: the global MSSS preconditioner, and the block-diagonal MSSS preconditioner. In Section 4, we use the distributed optimal control of the convection-diffusion equation to illustrate the performance of these two preconditioners and the new model order reduction algorithm. Section 5 presents how to extend such preconditioning techniques to 3D saddle-point problems. Section 6 draws conclusions and describes future work.

A companion technical report [30] is also available on-line and studies a wider class of PDE-constrained optimization problems. It contains more numerical experiments to illustrate the performance of this preconditioning technique. In [31], we study the preconditioning technique proposed in this manuscript applied to computational fluid dynamics (CFD) problems and evaluate their performance on CFD benchmark problems using the Incompressible Flow and Iterative Solver Software (IFISS) [37].

2. Problem formulation.

2.1. PDE-constrained optimization problem.

Consider the following PDE-constrained optimization problem

$$\begin{aligned} \min_{u,\, f} \ & \frac{1}{2}\|u-\hat{u}\|^2+\beta\|f\|^2, \\ s.t. \ & \mathcal{L}u=f, \quad \text{in } \Omega, \\ & u=u_D, \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where $\mathcal{L}$ is an operator, u the system state, f the system input, $\hat{u}$ the desired state of the system, Ω the domain, $\partial\Omega$ the corresponding boundary, β the weight of the system input in the cost function or regularization parameter and satisfies $\beta>0$. In this paper, we consider $\mathcal{L}=-\nabla^2$ for optimal control of the Poisson equation and $\mathcal{L}=-\epsilon\nabla^2+\overrightarrow{w}\cdot\nabla$ for optimal control of the convection-diffusion equation. Here $\overrightarrow{w}$ is a vector in Ω, ∇ is the gradient operator, and ϵ is a positive scalar. If we want to solve such a problem numerically, it is clear that we need to discretize these quantities involved at some point. There are two kinds of approaches. One is to derive the optimality conditions first and then discretize (*optimize-then-discretize*), and the other is to discretize the cost function and the PDE first and then optimize (*discretize-then-optimize*). For the problem of optimal control of the Poisson equation, both approaches lead to the same solution while different answers are reached for the problem of optimal control of the convection-diffusion equation; see [32]. Since our focus is on preconditioning for such problems, the *discretize-then-optimize* approach is chosen in this paper.

By introducing the weak formulation and discretizing (2.1) using the Galerkin method, the discrete analogue of the minimization problem (2.1) is

$$\begin{aligned} \min_{u,\, f} \ & \frac{1}{2}u^TMu-u^Tb+c+\beta f^TMf, \\ s.t. \ & Ku=Mf+d, \end{aligned} \tag{2.2}$$

ETNA
Kent State University
http://etna.math.kent.edu

where $K = [K_{i,j}] \in \mathbb{R}^{N\times N}$ is the stiffness matrix, $M = [M_{i,j}] \in \mathbb{R}^{N\times N}$, $M_{ij} = \int_\Omega \phi_i\phi_j d\Omega$ is the mass matrix and is symmetric positive definite, $b = [b_i] \in \mathbb{R}^N$, $b_i = \int_\Omega \hat{u}_i\phi_i d\Omega$, $c \in \mathbb{R}$, $c = \int_\Omega \hat{u}^2 d\Omega$, $d = [d_i] \in \mathbb{R}^N$, $d_i = -\sum_{j=N+1}^{N+\partial N} u_j \int_\Omega \nabla\phi_j \cdot \nabla\phi_i d\Omega$. Here ϕ_i $(i = 1, 2, \ldots N)$ and ϕ_j $(j = 1, 2, \ldots N, N+1, \ldots N+\partial N)$ form a basis of V_0^h and V_g^h, respectively. V_0^h and V_0^g represent the finite dimensional test space and solution space, respectively.

Considering the minimization problem (2.2), we introduce the Lagrangian function

$$\mathcal{J}(u, f, \lambda) = \frac{1}{2}u^T Mu - u^T b + c + \beta f^T Mf + \lambda^T(Ku - Mf - d),$$

where λ is the Lagrange multiplier. Then it is well-known that the optimal solution is given by finding u, f and λ, such that

$$\begin{aligned}
\nabla_u \mathcal{J}(u, f, \lambda) &= Mu - b + K^T\lambda = 0,\\
\nabla_f \mathcal{J}(u, f, \lambda) &= 2\beta Mf - M\lambda = 0,\\
\nabla_\lambda \mathcal{J}(u, f, \lambda) &= Ku - Mf - d = 0.
\end{aligned}$$

This yields the linear system

$$\underbrace{\begin{bmatrix} 2\beta M & 0 & -M \\ 0 & M & K^T \\ -M & K & 0 \end{bmatrix}}_{\mathcal{A}} \underbrace{\begin{bmatrix} f \\ u \\ \lambda \end{bmatrix}}_{x} = \underbrace{\begin{bmatrix} 0 \\ b \\ d \end{bmatrix}}_{g}. \tag{2.3}$$

The system (2.3) is of the saddle-point system type [4], i.e., the system matrix $\mathcal{A}$ is symmetric and indefinite. It has the following structure

$$\mathcal{A} = \begin{bmatrix} A & B^T \\ B & 0 \end{bmatrix}, \tag{2.4}$$

where $A \in \mathbb{R}^{n\times n}$ is symmetric positive definite, $B \in \mathbb{R}^{m\times n}$ has full rank.

The system matrix of the saddle-point system (2.3) is large and sparse. Preconditioned Krylov subspace methods, such as `MINRES` [27] and `IDR(s)` [38], are quite efficient for solving such systems.

2.2. Preconditioning of saddle-point systems. The performance of iterative solution methods highly depends on the choice of the preconditioners [33]. For numerical methods to solve saddle-point system (2.3) and the construction of preconditioners, we refer to [4, 26] for an extensive survey. In this paper, we study two types of preconditioners. The first exploits the MSSS structure of the blocks of the saddle-point system, whereas the second type exploits the global MSSS structure of the saddle-point system.

2.2.1. Block preconditioners. Recall from (2.4), if A is nonsingular, then $\mathcal{A}$ admits the following LDL^T factorization given by

$$\begin{bmatrix} 2\beta M & 0 & -M \\ 0 & M & K^T \\ -M & K & 0 \end{bmatrix} = \begin{bmatrix} I & & \\ 0 & I & \\ -\frac{1}{2\beta}I & KM^{-1} & I \end{bmatrix} \begin{bmatrix} 2\beta M & & \\ & M & \\ & & S \end{bmatrix} \begin{bmatrix} I & 0 & -\frac{1}{2\beta}I \\ & I & M^{-1}K^T \\ & & I \end{bmatrix},$$

ETNA
Kent State University
http://etna.math.kent.edu

where $S = -\left(\frac{1}{2\beta}M + KM^{-1}K^T\right)$ is the Schur complement.

The most difficult part for this factorization is to compute the Schur complement S because computing the inverse of a large sparse matrix is expensive both in time and memory. Meanwhile, solving the system $Sx = b$ is also expensive since S is a large and full matrix. Note that all the blocks of (2.3) have a structure that is called multilevel sequentially semiseparable (MSSS), which will be introduced in a later section. Then the Schur complement S also has the MSSS structure but with a larger semiseparable order. If we exploit the MSSS structure of (2.3), we can compute S in linear computational complexity.

In this paper, we first study the block-diagonal preconditioner $\mathcal{P}_1$ for the saddle-point system (2.3), where

$$\mathcal{P}_1 = \begin{bmatrix} 2\beta\hat{M} & & \\ & \hat{M} & \\ & & -\hat{S} \end{bmatrix}, \tag{2.5}$$

and where $\hat{M}$ is an approximation of the mass matrix M and $\hat{S}$ is an approximation of the Schur complement S. For $\hat{M}$ and $\hat{S}$ without approximation, i.e., $\hat{M} = M$ and $\hat{S} = S$, the preconditioned system $\mathcal{P}_1^{-1}\mathcal{A}$ has three distinct eigenvalues and GMRES computes the solution of the preconditioned system using at most three iterations.

To approximate $S = -\left(\frac{1}{2\beta}M + KM^{-1}K^T\right)$, $\hat{S} = -KM^{-1}K^T$ can be used for big to middle range of β while $\hat{S} = -\frac{1}{2\beta}M$ could be chosen for small β [32]. The block lower-triangular preconditioner $\mathcal{P}_2$, which has the following form

$$\mathcal{P}_2 = \begin{bmatrix} 2\beta\hat{M} & & \\ 0 & \hat{M} & \\ -M & K & \hat{S} \end{bmatrix}, \tag{2.6}$$

is studied in the technical report [30] and the performance comparison with the block-diagonal preconditioner $\mathcal{P}_1$ is also discussed.

2.2.2. Global preconditioners. Since all the blocks of the saddle-point system (2.3) have the MSSS structure, there exists a permutation matrix Ψ that permutes the saddle-point matrix with MSSS blocks into a single MSSS matrix. This gives

$$\tilde{\mathcal{A}}\tilde{x} = \tilde{g},$$

where $\tilde{\mathcal{A}} = \Psi\mathcal{A}\Psi^T$, $\tilde{x} = \Psi x$, and $\tilde{g} = \Psi g$ are permutations of $\mathcal{A}$, $\begin{bmatrix} f^T & u^T & \lambda^T \end{bmatrix}^T$, and $\begin{bmatrix} 0^T & b^T & d^T \end{bmatrix}^T$ in (2.3), respectively. This permutation will be introduced in the next section. After this permutation, the system matrix $\tilde{\mathcal{A}}$ is an MSSS matrix. We can compute an inexact LU factorization of $\tilde{\mathcal{A}}$ in linear computational complexity using MSSS matrix computations. This gives

$$\tilde{\mathcal{A}} \approx \tilde{L}\tilde{U}, \tag{2.7}$$

which can be used as a preconditioner. We call the factorization (2.7) the global preconditioner. Since no information of β is neglected during the permutation and factorization, the global preconditioner gives β-independent convergence, while this property for the standard block preconditioners $\mathcal{P}_1$ in (2.5) or $\mathcal{P}_2$ in (2.6) does not hold. This is a big advantage of the global preconditioner over the standard block preconditioners, which is illustrated by numerical experiments in Section 4.

3. Preconditioning using multilevel sequentially semiseparable matrix computations. Matrices in this paper will always be real and their dimensions are compatible for the matrix-matrix operations and the matrix-vector operations when their sizes are not mentioned.

3.1. Multilevel sequentially semiseparable matrices. The generator representation of the sequentially semiseparable matrices are defined by Definition 3.1.

DEFINITION 3.1 ([13]). *Let A be an $N \times N$ matrix with SSS matrix structure and let n positive integers $m_1,\ m_2,\ \cdots\ m_n$ satisfy $N = m_1 + m_2 + \cdots + m_n$, such that A can be written in the following block-partitioned form*

$$A_{ij} = \begin{cases} U_i W_{i+1} \cdots W_{j-1} V_j^T, & \text{if} \quad i < j; \\ D_i, & \text{if} \quad i = j; \\ P_i R_{i-1} \cdots R_{j+1} Q_j^T, & \text{if} \quad i > j, \end{cases}$$

where the superscript 'T' denotes the transpose of a matrix.

The sequences $\{U_i\}_{i=1}^{n-1}, \{W_i\}_{i=2}^{n-1}, \{V_i\}_{i=2}^{n}, \{D_i\}_{i=1}^{n}, \{P_i\}_{i=2}^{n}, \{R_i\}_{i=2}^{n-1}, \{Q_i\}_{i=1}^{n-1}$ are matrices whose sizes are listed in Table 3.1 and they are called generators of the SSS matrix A. With the generator representation defined in Definition 3.1, A can be denoted by

$$A = \mathcal{SSS}(P_s, R_s, Q_s, D_s, U_s, W_s, V_s).$$

TABLE 3.1
Generator sizes for the SSS matrix A in Definition 3.1.

Generators	U_i	W_i	V_i	D_i	P_i	R_i	Q_i
Sizes	$m_i \times k_i$	$k_{i-1} \times k_i$	$m_i \times k_{i-1}$	$m_i \times m_i$	$m_i \times l_i$	$l_{i-1} \times l_i$	$m_i \times l_{i+1}$

REMARK 3.2. The generators of an SSS matrix are not unique. There exist a series of nonsingular transformations between two different sets of generators for the same SSS matrix A.

REMARK 3.3. For an SSS matrix, only its generators are stored. If l_i and k_i are bounded by a small constant, then the memory consumption for storing such a matrix is linear with respect to the matrix size. This property is also introduced in [13].

Take $n = 4$, for example. The SSS matrix A is given by

$$A = \begin{bmatrix} D_1 & U_1 V_2^T & U_1 W_2 V_3^T & U_1 W_2 W_3 V_4^T \\ P_2 Q_1^T & D_2 & U_2 V_3^T & U_2 W_3 V_4^T \\ P_3 R_2 Q_1^T & P_3 Q_2^T & D_3 & U_3 V_4^T \\ P_4 R_3 R_2 Q_1^T & P_4 R_3 Q_2^T & P_4 Q_3^T & D_4 \end{bmatrix}. \tag{3.1}$$

With the generator representation of SSS matrices, basic operations such as addition, multiplication and inversion are closed under the SSS matrix structure and can be performed in linear computational complexity. Moreover, decompositions/factorizations such as the QR factorization [18, 20], the LU decomposition [22, 42], and the ULV decomposition [40] can also be computed in linear computational complexity and in a structure preserving way.

Similar to Definition 3.1 for SSS matrices, the generator representation for MSSS matrices, specifically the k-level SSS matrices, is defined as following.

DEFINITION 3.4. *The matrix A is said to be a k-level SSS matrix if all its generators are $(k-1)$-level SSS matrices. The 1-level SSS matrix is the SSS matrix that satisfies Definition 3.1.*

Most operations for SSS matrices can be extended to MSSS matrices, which yields linear computational complexity for MSSS matrices. MSSS matrices have many applications, one of them is the discretized partial differential equations (PDEs) [28].

ETNA
Kent State University
http://etna.math.kent.edu

Note that for a saddle-point system arising from the PDE-constrained optimization problem, all its blocks are MSSS matrices. This enables us to compute an LU factorization of all its blocks with MSSS matrix computations in linear computational complexity. However, the saddle-point matrix is not an MSSS matrix itself but just has MSSS blocks. It fails to compute an approximate LU factorization of the saddle-point system matrix by using MSSS matrix computations.

Lemma 3.5 explains how to permute a matrix with SSS blocks into a single SSS matrix. This property can be extended to matrices with MSSS blocks. This enables us to compute an LU factorization of the global saddle point matrix by using MSSS matrix computations in linear computational complexity.

LEMMA 3.5 ([34]). *Let A, B, C and D be SSS matrices with the following generator representations*

$$\begin{aligned} A &= \mathcal{SSS}(P_s^a, R_s^a, Q_s^a, D_s^a, U_s^a, W_s^a, V_s^a),\\ B &= \mathcal{SSS}(P_s^b, R_s^b, Q_s^b, D_s^b, U_s^b, W_s^b, V_s^b),\\ C &= \mathcal{SSS}(P_s^c, R_s^c, Q_s^c, D_s^c, U_s^c, W_s^c, V_s^c),\\ D &= \mathcal{SSS}(P_s^d, R_s^d, Q_s^d, D_s^d, U_s^d, W_s^d, V_s^d). \end{aligned}$$

Then there exists a permutation matrix Ψ with $\Psi\Psi^T = \Psi^T\Psi = I$, such that

$$\mathcal{T} = \Psi \begin{bmatrix} A & B \\ C & D \end{bmatrix} \Psi^T$$

and the matrix $\mathcal{T}$ is an SSS matrix. Its generator representation is

$$\mathcal{T} = \mathcal{SSS}(P_s^t, R_s^t, Q_s^t, D_s^t, U_s^t, W_s^t, V_s^t),$$

where

$$P_s^t = \begin{bmatrix} P_s^a & P_s^b & 0 & 0 \\ 0 & 0 & P_s^c & P_s^d \end{bmatrix}, \quad Q_s^t = \begin{bmatrix} Q_s^a & 0 & Q_s^c & 0 \\ 0 & Q_s^b & 0 & Q_s^d \end{bmatrix}, \quad D_s^t = \begin{bmatrix} D_s^a & D_s^b \\ D_s^c & D_s^d \end{bmatrix},$$

$$U_s^t = \begin{bmatrix} U_s^a & U_s^b & 0 & 0 \\ 0 & 0 & U_s^c & U_s^d \end{bmatrix}, \quad V_s^t = \begin{bmatrix} V_s^a & 0 & V_s^c & 0 \\ 0 & V_s^b & 0 & V_s^d \end{bmatrix},$$

$$W_s^t = \begin{bmatrix} W_s^a & & & \\ & W_s^b & & \\ & & W_s^c & \\ & & & W_s^d \end{bmatrix}, \quad R_s^t = \begin{bmatrix} R_s^a & & & \\ & R_s^b & & \\ & & R_s^c & \\ & & & R_s^d \end{bmatrix}.$$

Proof. For the case that all the diagonal blocks of A have the same size, and all the diagonal blocks of D also have the same size, i.e., $m_i^a = m^a$ and $m_i^d = m^d$, the permutation matrix Ψ has the following representation

$$\Psi = \begin{bmatrix} \begin{bmatrix} I_{m^a} \\ 0 \end{bmatrix} \otimes I_n & \begin{bmatrix} 0 \\ I_{m^d} \end{bmatrix} \otimes I_n \end{bmatrix}, \tag{3.2}$$

where $\otimes$ denotes the Kronecker product and I is the identify matrix with a proper size.

With the permutation matrix Ψ given by (3.2), the permuted matrix is

$$\mathcal{T} = \Psi \begin{bmatrix} A & B \\ C & D \end{bmatrix} \Psi^T. \tag{3.3}$$

ETNA
Kent State University
http://etna.math.kent.edu

It is not difficult to verify that the matrix $\mathcal{T}$ is an SSS matrix and its generators are given in Lemma 3.5.

For the case that sizes of diagonal blocks A and D are varying, let $\{m_i^a\}_{i=1}^n$ and $\{m_i^d\}_{i=1}^n$ represent the diagonal blocks sizes of A and D, respectively. The permutation matrix Ψ is

$$\Psi = \left[\text{blkdiag}\left(\left\{\begin{bmatrix} I_{m_i^a} \\ 0 \end{bmatrix}\right\}\right) \quad \text{blkdiag}\left(\left\{\begin{bmatrix} 0 \\ I_{m_i^d} \end{bmatrix}\right\}\right)\right], \tag{3.4}$$

where $\text{blkdiag}\left(\left\{\begin{bmatrix} I_{m_i^a} \\ 0 \end{bmatrix}\right\}\right)$ represents the block diagonal matrix with its diagonal blocks given by $\left\{\begin{bmatrix} I_{m_i^a} \\ 0 \end{bmatrix}\right\}_{i=1}^n$, and $\text{blkdiag}\left(\left\{\begin{bmatrix} 0 \\ I_{m_i^d} \end{bmatrix}\right\}\right)$ by $\left\{\begin{bmatrix} 0 \\ I_{m_i^d} \end{bmatrix}\right\}_{i=1}^n$.

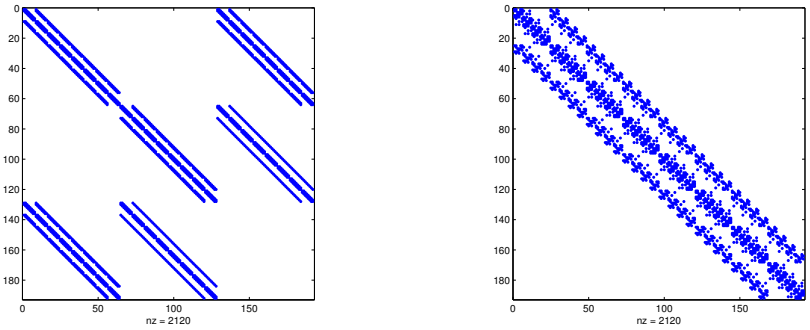
With the permutation matrix Ψ in (3.4), it is not difficult to show that the permuted matrix $\mathcal{T}$ given by (3.3) is an SSS matrix and its generators are given in Lemma 3.5. □

REMARK 3.6. Given a matrix with SSS blocks, one can apply Lemma 3.5 to permute it into a single SSS matrix by using a permutation matrix Ψ. However, this permutation matrix is not explicitly multiplied on both sides of the matrix to be permuted. The generators of the permuted matrix are combinations of the generators of its SSS blocks. This is illustrated by the generators representation of the permuted matrix in Lemma 3.5. Such permutations are cheaper to compute due to the fact that there is no matrix-matrix multiplication.

REMARK 3.7. Lemma 3.5 is for a 2×2 block matrix. It can be generalized to the case of matrices with a larger number of blocks.

REMARK 3.8. Extending Lemma 3.5 to the k-level SSS matrix case is also possible. If A, B, C, and D are k-level SSS matrices, then their generators are $(k-1)$-level SSS matrices. For the permuted k-level SSS matrix $\mathcal{T}$, its $(k-1)$-level SSS matrix generators with $(k-1)$-level SSS matrix blocks are permuted into a single $(k-1)$-level SSS matrix by applying Lemma 3.5 recursively.

The saddle-point system (2.3) derived from the optimal control of the convection-diffusion equation in 2D, discretized by using the Q_1 finite element method, has MSSS (2-level SSS) matrix blocks. The structure of the saddle-point matrix before and after permutation for mesh size $h = 2^{-3}$ are shown in Figure 3.1.



(a) Before permutation. (b) After permutation.

FIG. 3.1. *Structure of system matrix of* (2.3) *before and after permutation for* $h = 2^{-3}$.

3.2. Multilevel sequentially semiseparable preconditioners. The most important part of the PDE-constrained optimization problem is to solve a linear system of the saddle-point

type. In the following, we first introduce the LU factorization of MSSS matrices and then give a new model order reduction algorithm for SSS matrices, which is necessary for computing the LU factorization in linear computational complexity. For comparison, the conventional model order reduction algorithm [12] is also discussed.

3.2.1. LU **Factorization of multilevel sequentially semiseparable matrices.** The semiseparable order to be defined in Definition 3.9 plays an important rule in the MSSS matrix computations. Note that this type of structured matrices were studied by Dewilde et al. [13] and by Eidelman et al. [17] independently, and were called sequentially semiseparable matrices and quasiseparable matrices there, respectively. In this paper, we use the MATLAB style of notation for matrices, i.e., for a matrix A, $A(i:j, s:t)$ selects rows of blocks from i to j and columns of blocks from s to t of A.

DEFINITION 3.9 ([19]). *Let*

$$\textit{rank}\ A(k+1:n, 1:k) = l_k, \quad \textit{rank}\ A(1:k, k+1:n) = u_k, \quad k = 1, 2, \cdots, n-1,$$

where l_k and u_k, $k = 1, 2, \cdots, N-1$, are called the lower order numbers and upper order numbers of the matrix A, respectively. Let $r^l = \max l_k$, $r^u = \max u_k$, and call r^l and r^u the lower quasi-separable order and the upper quasi-separable order of A, respectively.

DEFINITION 3.10 ([34]). *The SSS matrix A with lower and upper semiseparable order r^l and r^u is called block $(r^l,\ r^u)$ semiseparable.*

The semiseparable order for 1-level SSS matrices defined in Definition 3.9 can be directly extended to the multilevel cases, which leads to Definition 3.11.

DEFINITION 3.11. *Let A be a $N \times N$ block k-level SSS matrix with its generators be $M \times M$ block $(k-1)$-level SSS matrices. Let*

$$\textit{rank}\ A(k+1:N, 1:k) = l_k, \quad \textit{rank}\ A(1:k, k+1:N) = u_k, \quad k = 1, 2, \cdots, N-1,$$

where l_k and u_k, $k = 1, 2, \cdots, N-1$, are called the k-level lower order numbers and the k-level upper order numbers of the k-level SSS matrix A, respectively. Let $r^l = \max l_k$, $r^u = \max u_k$, and call r^l and r^u the k-level lower semiseparable order and the k-level upper semiseparable order of the k-level SSS matrix A, respectively.

DEFINITION 3.12. *The k-level SSS matrix A with k-level lower and upper semiseparable order r^l and r^u is called k-level block $(r^l,\ r^u)$ semiseparable.*

By using these definitions, we can apply the following lemma to compute the LU factorization of a k-level SSS matrix.

LEMMA 3.13 ([22, 42]). *Let A be a strongly regular $N \times N$ block k-level sequentially semiseparable matrix of k-level block $(r^l,\ r^u)$ semiseparable and denoted by its generator representation $A = \mathcal{MSSS}(P_s,\ R_s,\ Q_s,\ D_s,\ U_s,\ W_s,\ V_s)$. Here we say that a matrix is strongly regular if its leading principal minors are nonsingular. Let $A = LU$ be its block LU factorization, then,*

1. *The block lower-triangular factor L is a k-level sequentially semiseparable matrix of k-level block $(r^L,\ 0)$ semiseparable and the block upper-triangular factor U is a k-level sequentially semiseparable matrix of k-level block $(0,\ r^U)$ semiseparable. Moreover, $r^L = r^l$ and $r^U = r^u$.*
2. *The factors L and U can be denoted by the generator representation*

$$L = \mathcal{MSSS}(P_s,\ R_s,\ \hat{Q}_s,\ D_s^L,\ 0,\ 0,\ 0),$$
$$U = \mathcal{MSSS}(0,\ 0,\ 0,\ D_s^U,\ \hat{U}_s,\ W_s,\ V_s).$$

where $\hat{Q}_s$, D_s^L, D_s^U and $\hat{U}_s$ are $(k-1)$-level sequentially semiseparable matrices. They are computed by the following algorithm:

Algorithm 1 LU factorization of a k-level SSS matrix A.

Input: $\{P_s\}_{s=2}^{N}, \{R_s\}_{s=2}^{N-1}, \{Q_s\}_{s=1}^{N-1}, \{D_s\}_{s=1}^{N}, \{U_s\}_{s=1}^{N-1}, \{W_s\}_{s=2}^{N-1}, \{Q_s\}_{s=2}^{N}$

1: $D_1 = D_1^L D_1^U$ (LU factorization of $(k-1)$-level SSS matrix)
2: Let $\hat{U}_1 = (D_1^L)^{-1} U_1$ and $\hat{Q}_1 = (D_1^L)^{-T} Q_1$
3: **for** $i = 2 : N-1$ **do**
4: **if** $i == 2$ **then**
5: $M_i = \hat{Q}_{i-1}^T \hat{U}_{i-1}$
6: **else**
7: $M_i = \hat{Q}_{i-1}^T \hat{U}_{i-1} + R_{i-1} M_{i-1} W_{i-1}$
8: **end if**
9: $\left(D_i - P_i M_i V_i^T\right) = D_i^L D_i^U$ (LU factorization of $(k-1)$-level SSS matrix)
10: Let $\hat{U}_i = (D_i^L)^{-1}(U_i - P_i M_i W_i)$, $\hat{Q}_i = (D_i^U)^{-T}(Q_i - V_i M_i^T R_i^T)$.
11: **end for**
12: $M_N = \hat{Q}_{N-1}^T \hat{U}_{N-1} + R_{N-1} M_{N-1} W_{N-1}$
13: $\left(D_N - P_N M_N V_N^T\right) = D_N^L D_N^U$ (LU factorization of $(k-1)$-level SSS matrix)

Output: $\{D_s^L\}_{s=1}^{N}, \{D_s^U\}_{s=1}^{N}, \left\{\hat{Q}_s\right\}_{s=1}^{N-1}, \left\{\hat{U}_s\right\}_{s=1}^{N-1}$

Proof. For the proof of this lemma, we refer to [22, 42]. ∎

REMARK 3.14. In Algorithm 1, the LU factorization of a 0-level SSS matrix is just the LU factorization of an ordinary matrix without SSS structure.

In Algorithm 1, for computing the LU factorization of a k-level SSS matrix, the matrix-matrix operations are performed on its $(k-1)$-level SSS generators, such as computing the recurrence of M_i in line 7 of Algorithm 1. Such operations lead to the growth of the $(k-1)$-level semiseparable order, which increases the computational complexity. This can be verified from the matrix-matrix operations introduced in [13, 17]. Take the 1-level SSS matrix A for example. The flops needed for computing A^2 is $\mathcal{O}(n^3 N)$, where n is the semiseparable order and N is the number of blocks of A [13]. To be specific, the following lemma is introduced.

LEMMA 3.15 ([17]). *Let A_1, A_2 be SSS matrices of lower semiseparable order m_1 and n_1, respectively. Then the product $A_1 A_2$ is of lower semiseparable order at most $m_1 + n_1$. Let A_1, A_2 be SSS matrices of upper semiseparable order m_2 and n_2, respectively. Then the product $A_1 A_2$ is upper semiseparable of order at most $m_2 + n_2$.*

REMARK 3.16. For a k-level SSS matrix, since the semiseparable order varies at different levels, results of Lemma 3.15 also hold for the k-level semiseparable order. But we do not know the exact upper bound of the $(k-1)$-level semiseparable order. We just know the $(k-1)$-level semiseparable order will increase.

Lemma 3.15 states that the semiseparable order grows by multiplying two SSS matrices, which also holds for adding two SSS matrices. There are similar results for multilevel SSS matrix multiplication and addition. Model order reduction is necessary to compute an LU factorization of the k-level SSS matrix A using Algorithm 1. The aim of model order reduction for a k-level SSS matrix A with its generator representation $A = \mathcal{MSSS}(P_s, R_s, Q_s, D_s, U_s, W_s, V_s)$ is to find $(k-1)$-level SSS matrices $\hat{P}_s$, $\hat{R}_s$, $\hat{Q}_s$, $\hat{U}_s$, $\hat{W}_s$, $\hat{V}_s$ of smaller order compared with P_s, R_s, Q_s, U_s, W_s, V_s, respectively, such that $\hat{A} = \mathcal{MSSS}(\hat{P}_s, \hat{R}_s, \hat{Q}_s, D_s, \hat{U}_s, \hat{W}_s, \hat{V}_s)$ is of k-level semiseparable order smaller than or equal to the minimal k-level semiseparable order of A. Meanwhile, $\hat{A}$ is an approximation of A up to a small tolerance ϵ, i. e., $\|\hat{A} - A\| < \epsilon$.

REMARK 3.17. Since the LU factorization of a k-level SSS matrix needs the model order reduction for $(k-1)$-level SSS matrices, the LU factorization in Lemma 3.13 is an

ETNA
Kent State University
http://etna.math.kent.edu

exact factorization for SSS matrices because no model order reduction is needed for ordinary matrices (0-level SSS matrices). It is an inexact factorization for the k-level ($k \geq 2$) SSS matrices.

For discretized one-dimensional PDEs on a regular grid, the system matrix has a certain SSS structure. The LU factorization introduced in Lemma 3.13 could be performed as a direct solver. For discretized higher dimensional PDEs on regular grids, this LU factorization can be used as an efficient preconditioner.

3.2.2. Approximate balanced truncation for SSS matrices. As introduced in the last section, the model order reduction plays a key role in the LU factorization of an MSSS matrix. In this subsection, we design a new model order reduction algorithm for SSS matrices. This new method exploits the correspondence between SSS matrices and linear time-varying (LTV) systems.

The SSS matrices have a realization of linear time-varying systems, which is studied by Dewilde et al. in [16]. Consider a mixed-causal system that is described by the following state-space model

$$\begin{bmatrix} x_{i+1}^c \\ x_{i-1}^a \end{bmatrix} = \begin{bmatrix} R_i & \\ & W_i \end{bmatrix} \begin{bmatrix} x_i^c \\ x_i^a \end{bmatrix} + \begin{bmatrix} Q_i \\ V_i \end{bmatrix} u_i,$$
$$y_i = \begin{bmatrix} P_i & U_i \end{bmatrix} \begin{bmatrix} x_i^c \\ x_i^a \end{bmatrix} + D_i u_i,$$

where x^c is the causal system state, x^a represents the anti-causal system state, u_i is the system input, and y_i is the system output. With zero initial system states and stacking all the input and output as $\bar{u} = \begin{pmatrix} u_1^T, & u_2^T, & \dots & u_N^T \end{pmatrix}^T$, $\bar{y} = \begin{pmatrix} y_1^T, & y_2^T, & \dots & y_N^T \end{pmatrix}^T$, the matrix $\mathcal{H}$ that describes the input-output behavior of this mixed-causal system, i.e., $\bar{y} = \mathcal{H}\bar{u}$, induces an SSS matrix structure. Take $N = 4$ for example, the matrix $\mathcal{H}$ is

$$\mathcal{H} = \begin{bmatrix} D_i & U_1V_2 & U_1W_2V_3 & U_1W_2W_3V_4 \\ P_2Q_1 & D_2 & U_2V_3 & U_2W_3V_4 \\ P_3R_2Q_1 & P_3Q_2 & D_3 & U_3V_4 \\ P_4R_3R_2Q_1 & P_4R_3Q_2 & P_4Q_3 & D_4 \end{bmatrix}.$$

Using the LTV systems realization for SSS matrices, we have the following lemma that gives a direct link between LTV systems order and the semiseparable order.

LEMMA 3.18 ([35]). *The lower and upper semiseparable order for an SSS matrix with minimal LTV system realization are* $\max\{l_i\}_{i=2}^{N}$ *and* $\max\{k_i\}_{i=1}^{M-1}$*, respectively. Here* $\{l_i\}_{i=2}^{M}$ *and* $\{k_i\}_{i=1}^{M-1}$ *are defined in Table 3.1.*

We describe the lemma in [35] more exactly by restricting the realization of an SSS matrix to be minimal in Lemma 3.18. It is not difficult to set an example of an SSS matrix with small semiseparable order, but its LTV systems realization is of larger order. Lemma 3.18 states that the order of the causal LTV system is equal to the lower semiseparable order of an SSS matrix, while the order of the anti-causal LTV system is equal to the upper semiseparable order. Thus, to reduce the semiseparable order of an SSS matrix is the same as reducing the order of its realization by mixed-causal LTV systems.

Model order reduction for LTV systems is studied in [10, 36]. In [36], a linear matrix inequality (LMI) approach was introduced to solve the Lyapunov inequalities to compute the controllability and observability Gramians. In [10], the low-rank Smith method was presented to approximate the square-root of the controllability and observability Gramians of LTV systems.

ETNA
Kent State University
http://etna.math.kent.edu

Since the causal LTV system and the anti-causal LTV system have similar structures that correspond to the strictly lower-triangular part and the strictly upper-triangular part of the matrix $\mathcal{H}$, respectively, we only consider the causal LTV system described by the following state-space model,

$$\begin{cases} x_{k+1} = R_k x_k + Q_k u_k, \\ y_k = P_k x_k, \end{cases} \tag{3.5}$$

over the time interval $[k_o, k_f]$ with zero initial states. The controllability Gramian $\mathcal{G}_c(k)$ and observability Gramian $\mathcal{G}_o(k)$ are computed by the following Stein recurrence formulas:

$$\begin{aligned} \mathcal{G}_c(k+1) &= R_k \mathcal{G}_c(k) R_k^T + Q_k Q_k^T, \\ \mathcal{G}_o(k) &= R_k^T \mathcal{G}_o(k+1) R_k + P_k^T P_k, \end{aligned} \tag{3.6}$$

with initial conditions $\mathcal{G}_c(k_o) = 0$ and $\mathcal{G}_o(k_f + 1) = 0$.

Note that the controllability Gramian $\mathcal{G}_c(k)$ and observability Gramian $\mathcal{G}_o(k)$ are positive definite if the system is completely controllable and observable or semi-definite if the system is partly controllable and observable. Thus their eigenvalues are non-negative and often have a large jump at an early stage [2, 3]. This suggests to approximate these two Gramians at each step by a low-rank approximation. In this paper, we just consider the case that the LTV systems are uniformly completely controllable and observable over the time interval, which means that both $\mathcal{G}_c$ and $\mathcal{G}_o$ are positive definite. This is reasonable because the SSS matrices considered in this paper correspond to uniformly completely controllable and observable LTV systems.

Since the controllability Gramian $\mathcal{G}_c(k)$ and observability Gramian $\mathcal{G}_o(k)$ have similar structure, we will only use the controllability Gramian $\mathcal{G}_c(k)$ to introduce the basic idea. The key point of the low-rank approximation is to substitute the factorization of the controllability Gramian $\mathcal{G}_c(k)$

$$\mathcal{G}_c(k) = L_c(k) L_c^T(k),$$

where $L_c(k) \in \mathbb{R}^{M \times M}$, by its low-rank factorization

$$\tilde{\mathcal{G}}_c(k) = \tilde{L}_c(k) \tilde{L}_c^T(k), \tag{3.7}$$

at each step k, where $\tilde{L}_c(k) \in \mathbb{R}^{M \times m_k}$ with m_k as the ϵ-rank of $\mathcal{G}_c(k)$, and $m_k < M$. Typically, m_k is set to be constant, i.e., $m_k = m$ at each step. It can be also chosen adaptively by setting a threshold ϵ for the truncated singular values. If $\mathcal{G}_c(k)$ is of low numerical rank, it is reasonable to use the rank m_k approximation (3.7) to approximate $\mathcal{G}_c(k)$.

The low-rank approximation of the controllability and observability Gramians for LTV systems is introduced in Algorithm 2.

In [9], the recursive low-rank Gramians method was used to approximate the Gramians of the linear time-invariant (LTI) systems. Such methods can also be applied to approximate the Gramians of the LTV systems. This is studied by the same author in an earlier reference [11]. In this manuscript, we study the connections between LTV systems and SSS matrices. Meanwhile, we extend the model order reduction algorithm for LTV systems to the model order reduction for SSS matrices. The low-rank approximation method in [9, 11] was used to approximate the Gramians of the LTV systems that the SSS matrix corresponds to and the approximate balanced truncation method was applied for the model order reduction. Even the low-rank approximation method in this manuscript and the one in [11] are quite similar, the novelty is that this algorithm has never been applied to reduce the rank of the off-diagonal blocks of structured matrices.

The balanced truncation approximates the LTV systems in the following way. The Hankel map, which maps the input from past to the output in the future, has the following definition for the LTV systems,

$$\mathcal{H}_k = \mathcal{O}_k \mathcal{C}_k, \tag{3.8}$$

where $\mathcal{O}_k$ and $\mathcal{C}_k$ are the state to outputs map, and input to state map at time instant k, respectively. Meanwhile, the following relation holds

$$\begin{aligned} \mathcal{G}_c(k) &= \mathcal{C}_k \mathcal{C}_k^T, \\ \mathcal{G}_o(k) &= \mathcal{O}_k^T \mathcal{O}_k, \end{aligned} \tag{3.9}$$

where $\mathcal{G}_c(k)$ and $\mathcal{G}_o(k)$ are the controllability Gramian and observability Gramian defined in (3.6), respectively.

ETNA
Kent State University
http://etna.math.kent.edu

The Hankel singular values $\sigma_{\mathcal{H}}$ are the singular values of the Hankel map, and it was computed via the following equations in the finite dimensional spaces.

$$\sigma^2_{\mathcal{H}_k} = \lambda(\mathcal{H}_k^T\mathcal{H}_k) = \lambda(\mathcal{C}_k^T\mathcal{O}_k^T\mathcal{O}_k\mathcal{C}_k) = \lambda(\mathcal{C}_k\mathcal{C}_k^T\mathcal{O}_k^T\mathcal{O}_k) = \lambda(\mathcal{G}_c(k)\mathcal{G}_o(k)).$$

It was shown in [43] that for any two positive definite matrices, there always exits a so-called contragredient transformation such that

$$\Lambda_k = T_k^{-1}\mathcal{G}_c(k)T_k^{-T} = T_k^T\mathcal{G}_o(k)T_k,$$

where $\Lambda_k = \operatorname{diag}(\lambda_{k_1}, \lambda_{k_2}, \cdots, \lambda_{k_M})$ is a diagonal matrix. With this contragredient transformation, we have

$$T_k^{-1}\mathcal{G}_c(k)\mathcal{G}_o(k)T_k = \Lambda_k^2.$$

This states that $\{\lambda_{k_i}\}_{i=1}^M$ are the Hankel singular values at time instant k. Such contragredient transformation brings the systems into a "balanced" form, which means that the controllability Gramian and observability Gramian of the system are equal to a diagonal matrix. For the LTV system (3.5), after such a transformation, the balanced LTV system is

$$\begin{cases} \bar{x}_{k+1} = T_{k+1}^{-1}R_kT_k\bar{x}_k + T_{k+1}^{-1}Q_ku_k, \\ y_k = P_kT_k\bar{x}_k. \end{cases} \tag{3.10}$$

Since for system (3.10), the controllability and observability Gramians are balanced, truncation can be performed to truncate the Hankel singular values that are below a set threshold. This could be done by using the left and right multipliers L_l and L_r that are defined by

$$L_l = \begin{bmatrix} I_m & 0 \end{bmatrix}, \; L_r = \begin{bmatrix} I_m \\ 0 \end{bmatrix},$$

where I_m is an $m \times m$ identity matrix and m is the reduced system dimension size. Then the reduced LTV system is

$$\begin{cases} \tilde{x}_{k+1} = \Pi_l(k+1)R_k\Pi_r(k)\tilde{x}_k + \Pi_l(k+1)Q_ku_k, \\ y_k = P_k\Pi_r(k)\tilde{x}_k, \end{cases} \tag{3.11}$$

where $\tilde{x}_k = L_l\bar{x}_k$, $\pi_l(k+1) = L_lT_{k+1}^{-1}$ and $\pi_r(k) = T_kL_r$.

The reduced LTV system (3.11) is computed via a projection method with the projector defined by $\pi(k) = \pi_r(k)\pi_l(k)$. This is because

$$\pi_l(k)\pi_r(k) = L_lT_k^{-1}T_kL_r = I_m$$

and

$$\pi(k)^2 = \pi_r(k)\pi_l(k)\pi_r(k)\pi_l(k) = \pi(k).$$

For the approximated Gramians $\tilde{\mathcal{G}}_c(k)$ and $\tilde{\mathcal{G}}_o(k)$, which are positive semi-definite, we have the following lemma, which states that there also exists a contragredient transformation such that

$$\Lambda'_k = \bar{T}_k^{-1}\tilde{\mathcal{G}}_c(k)\bar{T}_k^{-T} = \bar{T}_k^T\tilde{\mathcal{G}}_o(k)\bar{T}_k,$$

ETNA
Kent State University
http://etna.math.kent.edu

where Λ'_k is a diagonal matrix and

$$\Lambda'_k = \operatorname{diag}(\lambda'_{k_1},\ \lambda'_{k_2},\ \cdots,\ \lambda'_{k_m},\ 0,\ \cdots,\ 0). \tag{3.12}$$

LEMMA 3.19 ([43], Theorem 3). *Let $Q,\ P \in \mathbb{R}^{M\times M}$ be symmetric positive semidefinite and satisfy*

$$\textit{rank } Q = \textit{rank } P = \textit{rank } QP = m,$$

where $m \leq M$. Then there exists a nonsingular matrix $W \in \mathbb{R}^{M\times M}$ (contragredient transformation) and a positive definite diagonal matrix $\Sigma \in \mathbb{R}^{m\times m}$, such that

$$Q = W \begin{bmatrix} \Sigma & 0 \\ 0 & 0 \end{bmatrix} W^T, \quad P = W^{-T} \begin{bmatrix} \Sigma & 0 \\ 0 & 0 \end{bmatrix} W^{-1}.$$

Proof. For the proof of this lemma, we refer to [43]. ∎

We have already explained that the diagonal entries of the matrix Λ'_k in (3.12) are the Hankel singular values of the approximate Hankel map in (3.8). If the controllability Gramian $\mathcal{G}_c(k)$ and the observability Gramian $\mathcal{G}_o(k)$ are well approximated by $\tilde{\mathcal{G}}_c(k)$ and $\tilde{\mathcal{G}}_o(k)$ separately, then $\tilde{\mathcal{G}}_c(k)\tilde{\mathcal{G}}_o(k)$ also approximates $\mathcal{G}_c(k)\mathcal{G}_o(k)$ well. This means that the approximate Hankel singular values $\{\lambda'_{k_i}\}_{i=1}^m$ are close to the original Hankel singular values $\{\lambda_{k_i}\}_{i=1}^m$. In Algorithm 3, we show how to use the approximated Gramians $\tilde{\mathcal{G}}_c(k)$ and $\tilde{\mathcal{G}}_o(k)$ to compute the reduced system. By using the approximated Gramians, this method is called the approximate balanced truncation.

Algorithm 3 Approximate Balanced Truncation for LTV systems.

Input: LTV system $\{P_k\}_{k=2}^N$, $\{R_k\}_{k=2}^{N-1}$, $\{Q_k\}_{k=1}^{N-1}$, reduced system order m

1: Apply Algorithm 2 to compute the approximated Gramian factors $\left\{\tilde{L}_c(k)\right\}_{k=2}^N$ and $\left\{\tilde{L}_o(k)\right\}_{k=2}^N$
2: **for** k=2 : N **do**
3: Compute the singular value decomposition $\tilde{L}_c^T(k)\tilde{L}_o(k) = U_k\Sigma_k V_k^T$.
4: Let $\Pi_l(k) = \Sigma_k^{-\frac{1}{2}} V_k^T \tilde{L}_o^T(k)$, and $\Pi_r(k) = \tilde{L}_c(k) U_k \Sigma_k^{-\frac{1}{2}}$
5: **end for**
6: **for** k=1 : N **do**
7: **if** $k == 1$ **then**
8: $\tilde{Q}_k = \Pi_l(k+1)Q_k$
9: **else if** $k == N$ **then**
10: $\tilde{P}_k = P_k\Pi_r(k)$
11: **else**
12: $\tilde{Q}_k = \Pi_l(k+1)Q_k$, $\tilde{R}_k = \Pi_l(k+1)R_k\Pi_r(k)$, $\tilde{P}_k = P_k\Pi_r(k)$
13: **end if**
14: **end for**

Output: Reduced LTV system $\left\{\tilde{P}_k\right\}_{k=2}^N$, $\left\{\tilde{R}_k\right\}_{k=2}^{N-1}$, $\left\{\tilde{Q}_k\right\}_{k=1}^{N-1}$

We can prove the following lemma.

LEMMA 3.20. *Algorithm 3 is an approximate balanced truncation method for the LTV system (3.5).*

ETNA

Proof. According to Lemma 3.19, there exists a contragredient transformation $\bar{T}_k \in \mathbb{R}^{M\times M}$ such that

$$\Lambda_k' = \bar{T}_k^{-1}\tilde{\mathcal{G}}_c(k)\bar{T}_k^{-T} = \bar{T}_k^{T}\tilde{\mathcal{G}}_o(k)\bar{T}_k,$$

where Λ_k' is a diagonal matrix and

$$\Lambda_k' = \begin{bmatrix}\Sigma_k & 0\\ 0 & 0\end{bmatrix}.$$

Here

$$\Sigma_k = \operatorname{diag}(\lambda_{k_1}', \lambda_{k_2}', \cdots, \lambda_{k_m}'),$$

and $\{\lambda_{k_i}'\}_{i=1}^{m}$ are the singular values of $\tilde{L}_c^T(K)\tilde{L}_o(k)$, i.e.,

$$\tilde{L}_c^T(K)\tilde{L}_o(k) = U_k\Sigma_k V_k^T.$$

According to the proof of Lemma 3.19, the contragredient transformation $\bar{T}_k$ is computed via

$$\bar{T}_k = \begin{bmatrix}\tilde{L}_c(k) & N_o(k)\end{bmatrix}\begin{bmatrix}U_k & 0\\ 0 & \bar{V}_k\end{bmatrix}\begin{bmatrix}\Sigma_k & 0\\ 0 & \bar{\Sigma}_k\end{bmatrix}^{-\frac{1}{2}},$$

and the inverse of such transformation is computed by

$$\bar{T}_k^{-1} = \begin{bmatrix}\Sigma_k & 0\\ 0 & \bar{\Sigma}_k\end{bmatrix}^{-\frac{1}{2}}\begin{bmatrix}V_k^T & 0\\ 0 & \bar{U}_k^T\end{bmatrix}\begin{bmatrix}\tilde{L}_o(k)^T\\ N_c(k)^T\end{bmatrix},$$

where the columns of $N_o(k) \in \mathbb{R}^{M\times(M-m)}$ span the null space of $\tilde{G}_o(k)$, the columns of $N_c(k) \in \mathbb{R}^{M\times(M-m)}$ span the null space of $\tilde{G}_c(k)$, and the following singular value decomposition holds

$$\tilde{N}_c^T(k)\tilde{N}_o(k) = \bar{U}_k\bar{\Sigma}_k\bar{V}_k^T.$$

With this contragredient transformation $\bar{T}_k$, the left and right multipliers are computed via

$$\Pi_l(k) = \begin{bmatrix}I_m & 0\end{bmatrix}T_k^{-1} = \begin{bmatrix}I_m & 0\end{bmatrix}\begin{bmatrix}\Sigma_k & 0\\ 0 & \bar{\Sigma}_k\end{bmatrix}^{-\frac{1}{2}}\begin{bmatrix}V_k^T & 0\\ 0 & \bar{U}_k^T\end{bmatrix}\begin{bmatrix}\tilde{L}_o(k)^T\\ N_c(k)^T\end{bmatrix} = \Sigma_k^{-\frac{1}{2}}V_k^T\tilde{L}_o^T(k),$$

$$\Pi_r(k) = T_k\begin{bmatrix}I_m\\ 0\end{bmatrix} = \begin{bmatrix}\tilde{L}_c(k) & N_o(k)\end{bmatrix}\begin{bmatrix}U_k & 0\\ 0 & \bar{V}_k\end{bmatrix}\begin{bmatrix}\Sigma_k & 0\\ 0 & \bar{\Sigma}_k\end{bmatrix}^{-\frac{1}{2}}\begin{bmatrix}I_m\\ 0\end{bmatrix} = \tilde{L}_c(k)U_k\Sigma_k^{-\frac{1}{2}}.$$

And the projection is defined via

$$\Pi_k = \Pi_r(k)\Pi_l(k),$$

since $\Pi_l(k)\Pi_r(k) = I_m$ and $\Pi_k^2 = \Pi_k$. ∎

Note that the low-rank approximation together with the approximate balanced truncation for linear time-invariant (LTI) system is studied in [8, 9]. Only balanced truncation for linear time-varying (LTV) system is studied in [11].

For an SSS matrix $A = \mathcal{SSS}(P_s, R_s, Q_s, D_s, U_s, W_s, V_s)$ with lower semiseparable order M, we have already explained its LTV system realization. Thus, Algorithm 2 and Algorithm 3 can be performed to reduce the order of the causal LTV system (3.5), which corresponds to reduce the lower semiseparable order. This yields the approximated SSS matrix $\tilde{A} = \mathcal{SSS}(\tilde{P}_s, \tilde{R}_s, \tilde{Q}_s, D_s, U_s, W_s, V_s)$. For the strictly upper-triangular part of A, we first transpose it to the strictly lower-triangular form then perform Algorithm 2 and Algorithm 3. After this reduction, we transpose the reduced strictly lower-triangular part to the strictly upper-triangular form.

3.2.3. Hankel blocks approximation. To compare with our model order reduction method for SSS matrices, we describe the standard model order reduction algorithm in this part. It is called the Hankel blocks approximation in [12, 13]. The Hankel blocks of an SSS matrix are defined as following.

DEFINITION 3.21 ([12]). *Hankel blocks denote the off-diagonal blocks that extend from the diagonal to the northeast corner (for the upper case) or to the southwest corner (for the lower case).*

Take a 4×4 block SSS matrix A for example. The Hankel blocks for the strictly lower-triangular part are shown in Figure 3.2 by H_2, H_3 and H_4.

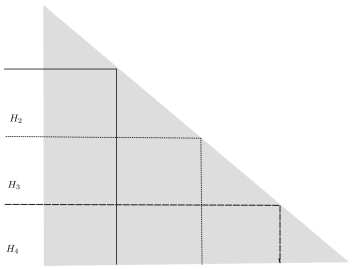

FIG. 3.2. *Hankel blocks of a* 4×4 *block SSS matrix.*

It is easy to verify that for the Hankel blocks $H_i,\ i = 2,\ \ldots,\ N$, the following relation holds

$$H_i = \mathcal{O}_i \mathcal{C}_i,\ i = 2,\ ,\ldots,\ N, \tag{3.13}$$

where $\mathcal{O}_i$ and $\mathcal{C}_i$ are the current state to the current and future output map and the past input to the current state map for system (3.5), respectively. Moreover, the following relations hold for $\mathcal{O}_i$ and $\mathcal{C}_i$.

$$\mathcal{O}_{i-1} = \begin{bmatrix} P_{i-1} \\ \mathcal{O}_i R_{i-1} \end{bmatrix},\ \text{for } i = 2,\ ,\ldots,\ N-1,\ \text{and } \mathcal{O}_N = P_N, \tag{3.14}$$

$$\mathcal{C}_{i+1} = \begin{bmatrix} R_i \mathcal{C}_i & Q_i \end{bmatrix},\ \text{for } i = 2,\ ,\ldots,\ N-1,\ \text{and } \mathcal{C}_2 = Q_1. \tag{3.15}$$

The two maps $\mathcal{C}_i$ and $\mathcal{O}_i$ also satisfy

$$\mathcal{G}_c(i) = \mathcal{C}_i \mathcal{C}_i^T,\ \mathcal{G}_o(i) = \mathcal{O}_i^T \mathcal{O}_i,$$

where $\mathcal{G}_c(i)$ and $\mathcal{G}_o(i)$ are the controllability Gramian and observability Gramian that satisfy (3.6).

The rank of the Hankel map H_i at time step i, i.e., the rank of the i-th Hankel block is the order of the states x_i of system (3.5); see [40]. The standard way to reduce the semiseparable order is given in [12, 13]. This standard approach is based on the realization theory of a given Hankel map for LTV systems that is introduced in [16, 40], i.e., according to the given Hankel map $\{H_i\}_{i=2}^N$, find a triple $\{P_k,\ R_k,\ Q_k\}$ that satisfy (3.13)–(3.15). By using the realization theory, it is also possible to get the reduced triple $\left\{\hat{P}_k,\ \hat{R}_k,\ \hat{Q}_k\right\}$ that approximates the Hankel map H_i in (3.13).

To do this approximation, first we need to transform the map $\mathcal{O}_i$ to the form that has orthonormal columns and transform the map $\mathcal{C}_i$ to the form that has orthonormal rows. These

ETNA
Kent State University
http://etna.math.kent.edu

two forms are called the left proper form and the right proper form [13, 12], respectively. We use the change of $\mathcal{C}_i$ to introduce the basic idea. The first step is to do a singular value decomposition (SVD) of the starting point $\mathcal{C}_2$, which gives

$$\mathcal{C}_2 = U_2 \Sigma_2 V_2^T,$$

and let $\bar{\mathcal{C}}_2 = V_2^T$. At this step, the map $\mathcal{C}_2$ is transformed to the form $\bar{\mathcal{C}}_2$ that has orthonormal rows. Due to the change of $\mathcal{C}_2$, to keep the Hankel map $H_i = \mathcal{O}_i \mathcal{C}_i$ unchanged, the map $\mathcal{O}_2$ is changed to

$$\bar{\mathcal{O}}_2 = \mathcal{O}_2 U_2 \Sigma_2.$$

Then the Hankel map satisfies

$$\bar{H}_2 = \bar{\mathcal{O}}_2 \bar{\mathcal{C}}_2 = \mathcal{O}_2 U_2 \Sigma_2 V_2^T = \mathcal{O}_2 \mathcal{C}_2 = H_2.$$

Since all these transformations have to be done on the triple $\{P_k,\ R_k,\ Q_k\}$, not on the maps, we have

$$\bar{Q}_1 = \bar{\mathcal{C}}_2 = V_2^T,$$

and

$$\bar{\mathcal{O}}_2 = \mathcal{O}_2 U_2 \Sigma_2 = \begin{bmatrix} P_2 \\ \mathcal{O}_3 R_2 \end{bmatrix} U_2 \Sigma_2,$$

which gives $\bar{P}_2 = P_2 U_2 \Sigma_2$ and $\bar{R}_2 = R_2 U_2 \Sigma_2$.

Now, suppose at step i, the map $\bar{\mathcal{C}}_i$ already has orthonormal rows, then for $\mathcal{C}_{i+1}$, we have

$$\mathcal{C}_{i+1} = \begin{bmatrix} \bar{R}_i \bar{\mathcal{C}}_i & Q_i \end{bmatrix} = \begin{bmatrix} \bar{R}_i & Q_i \end{bmatrix} \begin{bmatrix} \bar{\mathcal{C}}_i & \\ & I \end{bmatrix}. \tag{3.16}$$

By performing a singular value decomposition on $\begin{bmatrix} \bar{R}_i & Q_i \end{bmatrix}$, we have

$$\begin{bmatrix} \bar{R}_i & Q_i \end{bmatrix} = U_i \Sigma_i V_i^T. \tag{3.17}$$

Let $\begin{bmatrix} \bar{\bar{R}}_i & \bar{Q}_i \end{bmatrix} = V_i^T$, and partition V_i such that $V_i^T = \begin{bmatrix} V_{i_1}^T & V_{i_2}^T \end{bmatrix}$ to make the size of $V_{i_2}^T$ match the size of Q_i. Then let

$$\bar{Q}_i = V_{i_2}^T,\ \bar{\bar{R}}_i = V_{i_1}^T.$$

To keep the use of notations consistent, we reuse $\bar{R}_i$ to denote the transformed $\bar{R}_i$, i.e., $\bar{\bar{R}}_i$, this gives $\bar{R}_i = V_{i_1}^T$. By doing this, we have the transformed map

$$\bar{\mathcal{C}}_{i+1} = \begin{bmatrix} \bar{R}_i \bar{\mathcal{C}}_i & \bar{Q}_i \end{bmatrix} = \begin{bmatrix} \bar{R}_i & \bar{Q}_i \end{bmatrix} \begin{bmatrix} \bar{\mathcal{C}}_i & \\ & I \end{bmatrix} = V_i^T \begin{bmatrix} \bar{\mathcal{C}}_i & \\ & I \end{bmatrix}, \tag{3.18}$$

which also has orthonormal rows. This is due to

$$\bar{\mathcal{C}}_{i+1} \bar{\mathcal{C}}_{i+1}^T = V_i^T \begin{bmatrix} \bar{\mathcal{C}}_i & \\ & I \end{bmatrix} \begin{bmatrix} \bar{\mathcal{C}}_i^T & \\ & I \end{bmatrix} V_i = V_i^T \begin{bmatrix} \bar{\mathcal{C}}_i \bar{\mathcal{C}}_i^T & \\ & I \end{bmatrix} V_i = V_i^T V_i = I,$$

since $\bar{\mathcal{C}}_i$ also has orthonormal rows. Then the Hankel map at time step $i+1$ before and after such transformation has the following relation,

$$\mathcal{C}_{i+1} = U_i \Sigma_i \bar{\mathcal{C}}_{i+1}, \tag{3.19}$$

ETNA
Kent State University
http://etna.math.kent.edu

which can be checked by associating (3.16) and (3.17) with (3.18).

To keep the Hankel map at time step $i+1$ unchanged, the following relation needs to hold,

$$\bar{\mathcal{O}}_{i+1} = \mathcal{O}_{i+1} U_i \Sigma_i. \tag{3.20}$$

Since $\mathcal{O}_{i+1} = \begin{bmatrix} P_{i+1} \\ \mathcal{O}_{i+2} R_{i+1} \end{bmatrix}$, by letting $\bar{P}_{i+1} = P_{i+1} U_i \Sigma_i$ and $\bar{R}_{i+1} = R_{i+1} U_i \Sigma_i$, we have the transformed map

$$\bar{\mathcal{O}}_{i+1} = \begin{bmatrix} \bar{P}_{i+1} \\ \mathcal{O}_{i+2} \bar{R}_{i+1} \end{bmatrix}. \tag{3.21}$$

By checking (3.19)–(3.21), it is easy to get the unchanged Hankel map at time step $i+1$. Similar procedure can be applied to transform the map $\mathcal{O}_i$ to the form that has orthonormal columns. The procedure for transforming $\mathcal{C}_i$ and $\mathcal{O}_i$ is shown in Algorithm 4.

After transforming the map $\mathcal{O}_i$ and $\mathcal{C}_i$ into the form with orthogonal column basis and row basis, we can truncate unimportant column spaces and row spaces of $\mathcal{O}_i$ and $\mathcal{C}_i$, which gives the approximated Hankel map $\hat{H}_i = \hat{\mathcal{O}}_i \hat{\mathcal{C}}_i$.

3.3. Operations count for the two model order reduction methods. Given an SSS matrix $A = \mathcal{SSS}(P_S,\ R_s,\ Q_s,\ D_s,\ U_s,\ W_s,\ V_s)$, to compare the operations count of the approximate balanced truncation described by Algorithm 2-3 and the Hankel blocks approximation introduced in Algorithm 4, we assume that the generator sizes in Table 3.1 are uniform, i.e., $m_i = n$ and $k_i = l_i = M$. Here N is the number of SSS blocks (LTV system time steps), M is the unreduced LTV system order, and $N \gg M \gg n$. The reduced SSS matrix is $\tilde{A} = \mathcal{SSS}(\hat{P}_s,\ \hat{R}_s,\ \hat{Q}_s,\ D_s,\ \hat{U}_s,\ \hat{W}_s,\ \hat{V}_s)$, where $\hat{k}_i = \hat{l}_i = m$, m is the reduced semiseparable order and $m \ll M$.

In this paper, we measure the operations count by the floating-point operations (flops). To count the operations of the approximate balanced truncation, we first count the operations for the low-rank approximation in Algorithm 2. In the forward recursion, the singular value decomposition uses

$$m^2 M + (m+n)^2 M(N-2) \tag{3.22}$$

flops. In this recursion, two matrix-matrix product are computed in each iteration. This consumes

$$mM^2(N-2) + m^2 M(N-1) \tag{3.23}$$

flops. Adding (3.22) and (3.23) gives the total flop count for the forward low-rank approximation,

$$m^2 M + (m+n)^2 M(N-2) + mM^2(N-2) + m^2 M(N-1). \tag{3.24}$$

Since the forward low-rank approximation and the backward low-rank approximation are symmetric in computing, the flop count for the backward low-rank approximation is equal to (3.24). Then the flop count $\mathcal{F}_l$ for the low-rank approximation Algorithm 2 is

$$\mathcal{F}_l = 2mM^2N + 4m^2MN + 4mnMN + 2n^2MN - 4(m+n)^2M - 4mM^2. \tag{3.25}$$

ETNA
Kent State University
http://etna.math.kent.edu

Next we count the operations of the approximate balanced truncation Algorithm 3. First, to compute $\Pi_l(k)$ and $\Pi_r(k)$, the flop count is

$$\left(m^2M + m^3 + 2(m^2 + m^2M)\right)(N-1), \tag{3.26}$$

and the flop count to compute the reduced LTV system is

$$2mnM(N-1) + (mM^2 + m^2M)(N-2). \tag{3.27}$$

Thus the total flop count $\mathcal{F}_a$ for the approximate balanced truncation is the summation of (3.26) and (3.27), which gives

$$\mathcal{F}_a = (M^2 + mM + 2nM)N - 2mn(M + m + n). \tag{3.28}$$

Then we have the total flop count $\mathcal{F}_{la}$ of the approximate balanced truncation by adding (3.25) to (3.28). Since we have $N \gg M \gg m,\ n$, we just use the $\mathcal{O}(\cdot)$ to denote the total flop count. Thus, we have

$$\mathcal{F}_{la} = \mathcal{O}\left((2m+1)M^2N\right). \tag{3.29}$$

Similarly, the operations count $\mathcal{F}_h$ for the Hankel blocks approximation in Algorithm 4 is

$$\mathcal{F}_h = 4M^3N + 6nM^2N + 2(n^2+2n)MN - 8M^3 - 12nM^2 + 2(n^2-3n)M + 2n^2, \tag{3.30}$$

which can be written in the $\mathcal{O}(\cdot)$ notation as

$$\mathcal{F}_h = \mathcal{O}(4M^3N).$$

Since $N \gg M \gg m$, by comparing the flop count $\mathcal{F}_{la}$ for the approximate balanced truncation in (3.29) with the flop count $\mathcal{F}_h$ for the Hankel blocks approximation in (3.30), we see that the approximate balanced truncation algorithm is computationally cheaper than the Hankel blocks approximation for the model order reduction of SSS matrices.

REMARK 3.22. We can see from $\mathcal{F}_{la}$ in (3.29) and $\mathcal{F}_h$ in (3.30), that the flop count is linear with N for both method, where N denotes the number of blocks of an SSS matrix. Moreover, the size of the SSS matrix equals to nN and $n \ll N$. Thus, both methods give computational complexity that is linear with the matrix size.

3.4. Flowchart of preconditioning by using MSSS matrix computations. We have already described the MSSS matrix computations and how to compute a preconditioner using such matrix computations. The flowchart shown in Figure 3.3 illustrates how to compute a preconditioner for the PDE-constrained optimization problem (2.1).

4. Numerical experiments. In this section, we study the problem of optimal control of the convection-diffusion equation that is introduced in Example 4.1. First, we compare the performance of our model order reduction algorithm with the conventional model order reduction algorithm. Next we test the global MSSS preconditioner and the block diagonal MSSS preconditioner. Numerical experiments in [30] also show the advantage of the global MSSS preconditioner over the lower-triangular block MSSS preconditioner for the PDE-constrained optimization problems. The superiority of the global MSSS preconditioner to the block preconditioners that are computed by the multigrid methods for computational fluid dynamics (CFD) problems is illustrated in [31].

EXAMPLE 4.1 ([32]). Let $\Omega = \{(x,y) | 0 \le x \le 1, 0 \le y \le 1\}$ and consider the problem

$$\begin{aligned} \min_{u,f} \frac{1}{2}\|u - \hat{u}\| + \frac{\beta}{2}\|f\|^2, \\ s.t.\ -\epsilon\nabla^2 u + \overrightarrow{\omega}.\nabla u = f \text{ in } \Omega, \\ u = u_D \text{ on } \Gamma_D, \end{aligned}$$

ETNA
Kent State University
http://etna.math.kent.edu

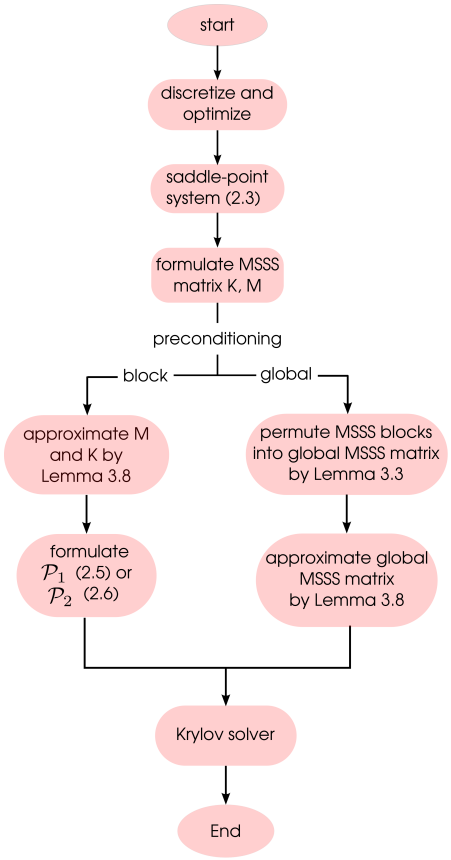

FIG. 3.3. *Flowchart for MSSS preconditioning of PDE-constrained optimization problem.*

where $\Gamma_D = \partial\Omega$ and

$$u_D = \begin{cases} (2x-1)^2(2y-1)^2 & \text{if } 0 \le x \le \frac{1}{2}, \text{ and } 0 \le y \le \frac{1}{2}, \\ 0 & \text{otherwise.} \end{cases}$$

ϵ is a positive scalar, $\overrightarrow{\omega} = (cos(\theta),\ sin(\theta))^T$ is the unit directional vector and the prescribed state $\hat{u} = 0$.

The numerical experiments are performed on a laptop with Intel Core 2 Duo P8700 CPU of 2.53 GHz and 8Gb memory in Matlab R2010b. The iterative solver is stopped by either reducing the 2-norm of the residual by a factor of 10^{-6} or reaching the maximum number of iterations that is set to be 100 in this manuscript. Note that there are three unknowns on each grid point. The problem sizes $3.07e+03$,$1.23e+04$, $4.92e+04$ and $1.97e+05$ correspond to the mesh sizes $h = 2^{-5}$, 2^{-6}, 2^{-7}, and 2^{-8}, respectively. In the following tables, the maximum semiseparable order for the model order reduction is given in the brackets following the problem size. The "preconditioning" columns report the time to compute the preconditioner; the "MINRES" or "IDR(s)" columns give the time to solve the saddle point problem by using such Krylov solver; the "total" columns show the summation of them. All the times are measured in seconds.

4.1. Comparison of two model order reduction algorithms. Here we test the performance of the two model order reduction algorithms. Consider the preconditioning of optimal

ETNA
Kent State University
http://etna.math.kent.edu

control of the convection-diffusion equation described by Example 4.1. For the block-diagonal preconditioner $\mathcal{P}_1$ that is computed by the approximate balanced truncation algorithm and the Hankel blocks approximation method, the results for different ϵ and β are shown in Tables 4.1–4.8, while θ is set to be $\frac{\pi}{5}$ for all the experiments.

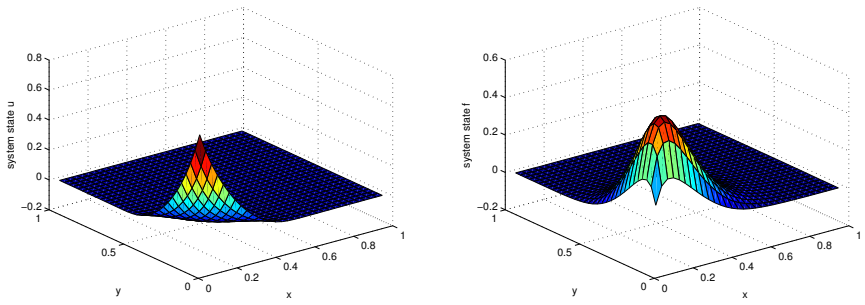
The results in Tables 4.1–4.8 show that the time to compute the preconditioner and iteratively solve the saddle-point system is linear in the problem size, which illustrates that the MSSS preconditioning technique has linear computational complexity. This shows that for the same group of ϵ and β, the block MSSS preconditioners computed by the approximate balanced truncation and Hankel blocks approximation methods give mesh size independent convergence. Moreover, the number of iterations for the block MSSS preconditioners computed by both model order reduction algorithms are the same.

REMARK 4.1. As shown by (3.29) and (3.30), the approximate balanced truncation is computationally cheaper than the Hankel blocks approximation and both algorithms have linear computational complexity. This is illustrated by the time to compute the preconditioners by these two methods for the same group of β and ϵ in Tables 4.1–4.8.

The optimal solution of the system states and input for $\beta = 10^{-2}$, $\epsilon = 10^{-1}$ and $h = 2^{-5}$ are shown in Figure 4.1(a) and Figure 4.1(b).



(a) Optimal system states u. (b) Optimal system input f.

FIG. 4.1. *Solution of the system states and input for* $\beta = 10^{-2}$, $\epsilon = 10^{-1}$ *and* $h = 2^{-5}$.

The block-diagonal and block lower-triangular MSSS preconditioners computed by these two model order reduction algorithms are also tested on the problems of optimal control of the Poisson equation and optimal control of the convection-diffusion equation in [30]. These results in [30] are consistent with the conclusions we draw here on the performance of these two model order reduction algorithms and the performance of such block MSSS preconditioners.

4.2. Comparison of preconditioners. In this subsection, we test the performance of the block-diagonal MSSS preconditioner and the global MSSS preconditioner. For the block diagonal MSSS preconditioner, from Tables 4.1–4.8 we have seen that with the decrease of β, the number of iterations increases slightly for the same problem size and ϵ. This is due to the $\frac{1}{2\beta}M$ term, which plays an increasingly more important role with the decrease of β, while this term is often neglected in the preconditioner $\mathcal{P}_1$ in (2.5) for large and medium value of β [32]. For smaller β, the computational results for the block-diagonal MSSS preconditioner are shown in Tables 4.9-4.10. For the preconditioners tested here, the Hankel blocks approximation method is chosen as the model order reduction algorithm. Results for the preconditioners computed by the approximate balanced truncation can be found in [30].

TABLE 4.9
Results for the block-diagonal MSSS preconditioner (2.5) for $\beta = 10^{-3}$, $\epsilon = 10^{-1}$.

problem size	iterations	preconditioning (sec.)	MINRES (sec.)	total (sec.)

1.23e+04 (3)	34	1.31	7.61	8.92
4.92e+04 (3)	34	4.26	19.83	24.09
1.97e+05 (5)	34	17.39	61.82	79.21

TABLE 4.10
Results for the block-diagonal MSSS preconditioner (2.5) for $\beta = 10^{-4}$, $\epsilon = 10^{-1}$.

problem size	iterations	preconditioning (sec.)	MINRES (sec.)	total (sec.)
3.07e+03 (3)	82	0.45	4.91	5.36
1.23e+04 (3)	82	1.31	11.91	13.22
4.92e+04 (3)	80	4.34	34.83	39.17
1.97e+05 (5)	80	17.89	133.28	141.17

As shown in Tables 4.9–4.10, with the decrease of β from 10^{-3} to 10^{-4}, the number of iterations at least doubled. Clearly if β is small, the block-diagonal MSSS preconditioner $\mathcal{P}_1$ cannot give satisfactory results. Alternatively, for small β, we can choose the block-diagonal MSSS preconditioner as follows

$$\mathcal{P}_1 = \begin{bmatrix} 2\beta\hat{M} & & \\ & \hat{M} & \\ & & -\frac{1}{2\beta}\hat{M} \end{bmatrix}. \tag{4.1}$$

The computational results of this preconditioner for $\beta = 10^{-4}$ are given in Table 4.11. The maximum number of iterations is set to 100.

TABLE 4.11
Results for the block-diagonal MSSS preconditioner (4.1) for $\beta = 10^{-4}$, $\epsilon = 10^{-1}$.

problem size	iterations	preconditioning (sec.)	MINRES (sec.)	convergence
3.07e+03 (5)	100	0.35	6.73	no convergence
1.23e+04 (5)	100	1.17	17.97	no convergence
4.92e+04 (5)	100	4.19	44.93	no convergence
1.97e+05 (5)	100	15.72	156.89	no convergence

The results in Tables 4.10–4.11 show that the block-diagonal MSSS preconditioner does not give satisfactory performance when β becomes so small. In those tables, "no convergence" means that the 2-norm of the residual does not converge to desired accuracy within 100

ETNA
Kent State University
http://etna.math.kent.edu

iterations. This is due to the fact that the Schur complement is difficult to approximate for small β.

Recall from Section 2 that we can permute the saddle-point system with MSSS blocks into a global MSSS system. Due to the indefiniteness of the global MSSS preconditioner, `MINRES` is not suitable to iteratively solve the preconditioned saddle-point system. Instead, the induced dimension reduction (`IDR(s)`) method [41] is chosen as the Krylov solver. To compare with the results for the block-diagonal MSSS preconditioner in Tables 4.9–4.11, we apply the global MSSS preconditioner to the same test case. The results are given in Tables 4.12–4.13.

TABLE 4.12

1.23e+04 (6)	2	1.16	0.24	1.40
4.92e+04 (8)	2	4.46	0.66	5.12
1.97e+05 (10)	2	18.29	2.21	20.50

TABLE 4.13
Results for the global MSSS preconditioner for $\beta = 10^{-4}$ *and* $\epsilon = 10^{-1}$.

problem size	iterations	preconditioning (sec.)	IDR(4) (sec.)	total (sec.)
3.07e+03 (4)	2	0.38	0.13	0.51
1.23e+04 (6)	2	1.15	0.24	1.39
4.92e+04 (7)	2	4.23	0.64	4.87
1.97e+05 (9)	2	17.87	2.18	20.05

Even though it takes slightly more time to compute the global MSSS preconditioner than to compute the block-diagonal MSSS preconditioner, much less time is needed for the `IDR(s)` method to solve the preconditioned system by the global MSSS preconditioner. Meanwhile, the total time in Tables 4.12–4.13 scales linearly with the problem size.

REMARK 4.2. By comparing the computational results of the global MSSS preconditioner with that of the block-diagonal MSSS preconditioner, we find that for the same numerical test with the same group of β and ϵ that the number of iterations is reduced significantly by the global MSSS preconditioner. Meanwhile, the global MSSS preconditioner gives both mesh size and β independent convergence. This makes the global MSSS preconditioner superior to the block preconditioners.

5. Preconditioning for optimal control of 3D problems. As analyzed in Section 3.2.1, to do an LU factorization of a k-level SSS matrix, the model order reduction of a $(k-1)$-level SSS matrix is needed. Therefore, to compute a preconditioner for 3D problems using MSSS matrix computations, model order reduction for 2-level SSS matrices is needed. Since the model order reduction for two and higher level SSS matrices is still an open problem, only preliminary results are given in this section for solving the following problem of optimal control of the 3D Poisson equation

$$\begin{aligned} \min_{u,f} \frac{1}{2}\|u-\hat{u}\| + \frac{\beta}{2}\|f\|^2, \\ s.t. \; -\nabla^2 u = f \text{ in } \Omega, \\ u = u_D \text{ on } \partial\Omega, \end{aligned} \tag{5.1}$$

ETNA
Kent State University
http://etna.math.kent.edu

where $\Omega = \{(x, y, z) | 0 \le x \le 1, 0 \le y \le 1, 0 \le z \le 1\}$ and

$$u_D = \begin{cases} \sin(2\pi y), & \text{if } x = 0,\ 0 \le y \le 1,\ z = 0; \\ -\sin(2\pi y), & \text{if } x = 1,\ 0 \le y \le 1,\ z = 0; \\ 0, & \text{elsewhere.} \end{cases}$$

The discretized analog of problem (5.1) is

$$\min_{u,\ f} \ \frac{1}{2}\|u - \hat{u}\|^2 + \beta\|f\|^2,$$
$$s.t.\ Ku = Mf + d,$$

where

$$K = \begin{bmatrix} D & -L & & & \\ -L & D & -L & & \\ & -L & D & \ddots & \\ & & \ddots & \ddots & -L \\ & & & -L & D \end{bmatrix}. \tag{5.2}$$

Here the matrices D and L in K are 2-level SSS matrices, M is the 3D mass matrix that has the same structure as K, d is a vector corresponding to the given boundary condition. To compute the optimal solution of (5.1), a system of the form (2.3) needs to be solved. Here we again study two types of preconditioners: the block-diagonal MSSS preconditioner and the global MSSS preconditioner.

5.1. Block-diagonal preconditioner. In this subsection, we test the block-diagonal preconditioner for large and medium β. The block-diagonal preconditioner $\mathcal{P}_1$ (2.5) is used. Here the Schur complement is approximated by $\hat{K}M^{-1}\hat{K}^T$, where $\hat{K}$ is an approximation of K by MSSS matrix computations.

To approximate the symmetric positive definite matrix K, we compute its approximate Cholesky factorization with MSSS matrix computations. At the k-th step of the Cholesky factorization, the Schur complement is computed via

$$\begin{cases} S_k = D, & \text{if } k = 1, \\ S_k = D - LS_{k-1}^{-1}L, & \text{if } k \ge 2. \end{cases} \tag{5.3}$$

Since D and L are 2-level SSS matrices, S_k is also a 2-level SSS matrix. In the recurrence (5.3), both the 2-level and 1-level semiseparable orders of S_k increase as k increases. Model order reduction for 2-level and 1-level SSS matrices are necessary, of which the model order reduction for 2-level SSS matrix is still an open problem. Here we use an alternative method to approximate the Schur complement with lower 2-level semiseparable order.

As pointed out in [14], for a symmetric positive definite matrix obtained from the discretization of PDEs with constant coefficients, all its subsequent Schur complements are also symmetric positive definite and converge to a fixed point matrix S_∞ with a fast rate. In [15], Dewilde et al. used a hierarchical partitioning of the 3D matrix K (5.2) and did computations on 2D matrices using the 1-level SSS matrix computations to precondition the 3D Poisson equation on an $8 \times 8 \times 8$ regular grid. Due to the fact that 1-level SSS matrix computations were performed on 2D matrices, the linear computational complexity is lost. Note that there is no numerical experiment in [15] to study the performance of such preconditioning technique for any Krylov solver.

ETNA
Kent State University
http://etna.math.kent.edu

In this manuscript, we extend the method in [15] to the optimal control of 3D Poisson equation in the following ways. Instead of using the hierarchical partitioning of a 3D matrix, we use the 3-level SSS matrix formulation. This avoids cutting on "layers" that is introduced in [15] to bound the 2-level semiseparable order. We exploit the fast convergence property of the Schur complements of symmetric positive definite matrices to bound the 2-level semiseparable order. As analyzed in Section 3.1, the 1-level and 2-level semiseparable order both grow in computing the Schur complements in (5.3). To reduce the 1-level semiseparable order, we can apply the approximate balanced truncation or the Hankel blocks approximation that are introduced in Section 3.2. To bound the 2-level semiseparable order, we use a different approach. We compute the Schur complements of the first k_r steps using MSSS matrix computations. Here k_r is a small constant that can be chosen freely. By using the Schur complement at step k_r to replace the Schur complements, i.e., we have the following recursions for the Schur complements

$$\begin{cases} S_k = D, & \text{if } k = 1, \\ S_k = D - LS_{k-1}^{-1}L, & \text{if } 2 \le k \le k_r, \\ S_k = S_{k_r}, & \text{if } k > k_r. \end{cases}$$

Since only the Schur complements are computed in the first k_r steps, the 2-level semiseparable order is bounded. This also bounds the computational complexity. Due to the fast convergence property, the Schur complement at step k_r gives an efficient approximation of the Schur complements afterwards. We also extend the fast convergence property of the Schur complements for the symmetric positive definite matrix to the symmetric indefinite matrix case. This extension enables us to compute a good approximation of the 3D global saddle-point matrix, which gives an efficient global MSSS preconditioner.

Here we apply the block-diagonal MSSS preconditioner (2.5) and the `MINRES` method to iteratively solve the saddle-point system. The computational results are reported in Tables 5.1–5.3. Note that if the mesh size h is halved, the problem size grows by a factor of 8. Besides, there are three unknowns per grid point. The 1-level semiseparable order is set to be 6 for all the numerical experiments in this part. The iterative solver is stopped if the 2-norm of the residual is reduced by a factor of 10^{-6}. The Hankel blocks approximation is chosen as the model order reduction method. The "preconditioning", "MINRES", and "total" columns have the same meanings as in the previous tables.

We can see from Tables 5.1–5.3 that for fixed h and β, the number of iterations decreases as k_r increases. A small k_r is needed to compute the preconditioner efficiently. With the increase of k_r, the time to compute the preconditioner also increases. Since only the Schur complements in the first k_r steps are computed, the time to compute the preconditioner increases less than linearly while halving the mesh size h. This is illustrated by the "preconditioning" columns in Tables 5.1–5.3. Moreover, by choosing proper k_r, the block MSSS preconditioner also gives virtually mesh size independent convergence and regularization parameter almost independent convergence while the computational complexity is less than linear, which can also be observed from Tables 5.1–5.3.

5.2. Global preconditioners. In the previous subsection, we studied the performance of the block MSSS preconditioner for the optimal control of 3D Poisson equation. Here we

ETNA
Kent State University
http://etna.math.kent.edu

extend the technique to bound the 2-level semiseparable order of the Schur complements for the symmetric indefinite system. While the analysis in [14] holds only for the symmetric positive definite matrix case, our numerical experiments illustrate that the fast convergence property of the Schur complements also holds for the symmetric indefinite case.

The saddle-point system obtained by using the *discretize-then-optimize* approach has the following form,

$$\mathcal{A} = \begin{bmatrix} 2\beta M & 0 & -M \\ 0 & M & K^T \\ -M & K & 0 \end{bmatrix}, \tag{5.4}$$

where K is the stiffness matrix as given in (5.2), and M is the mass matrix. Since all these matrices are from the discretization of 3D PDEs, K and M have the same 3-level SSS structure as shown in (5.2). Here we can apply Lemma 3.5 again to permute the global saddle-point matrix $\mathcal{A}$ (5.4) into a global MSSS matrix $\bar{\mathcal{A}}$. The permuted global saddle-point matrix $\bar{\mathcal{A}}$ has the same MSSS structure as subblocks of $\mathcal{A}$, i.e.,

$$\bar{\mathcal{A}} = \begin{bmatrix} \bar{D} & \bar{L} & & & \\ \bar{L} & \bar{D} & \bar{L} & & \\ & \bar{L} & \bar{D} & \ddots & \\ & & \ddots & \ddots & \bar{L} \\ & & & \bar{L} & \bar{D} \end{bmatrix},$$

where $\bar{D}$ and $\bar{L}$ are obtained via Lemma 3.5. Since $\bar{\mathcal{A}}$ is a symmetric indefinite matrix, its Schur complements in computing the LU factorization are also indefinite. To compute an LU factorization, the Schur complements are computed via the following recursions,

$$\begin{cases} \bar{S}_k = \bar{D}, & \text{if } k = 1, \\ \bar{S}_k = \bar{D} - \bar{L}\bar{S}_{k-1}^{-1}\bar{L}, & \text{if } k \geq 2. \end{cases}$$

Due to the indefiniteness of $\bar{D}$, the Schur complements are also indefinite. We apply the same method as introduced in the previous section: we compute the Schur complements of the first k_r steps and use the Schur complement at step k_r to approximate the Schur complements afterwards. This gives,

$$\begin{cases} \bar{S}_k = \bar{D}, & \text{if } k = 1, \\ \bar{S}_k = \bar{D} - \bar{L}\bar{S}_{k-1}^{-1}\bar{L}, & \text{if } 2 \leq k \leq k_r, \\ \bar{S}_k = \bar{S}_{k_r}, & \text{if } k > k_r. \end{cases}$$

By using this approximation for the permuted global system, we can compute the global MSSS preconditioner and apply it to iteratively solve the saddle-point system. The computational results are given in Tables 5.4–5.6.

		3	9	322.00	1328.26	1650.26
		4	8	1503.76	2218.80	3722.56

Since we just compute the first few steps of the Schur complements, the computational complexity of constructing the global MSSS preconditioner is less than linear, which can be observed from the "preconditioning" columns for the same k_r in Tables 5.4–5.6. The number of iterations decreases as k_r increases for the same β and h. By using a small k_r, we have already

reduced the number of iterations significantly by the global MSSS preconditioner compared with the block-diagonal MSSS preconditioner. Moreover, the global MSSS preconditioner gives virtually both mesh size h and regularization parameter β independent convergence for properly chosen k_r.

REMARK 5.1. Compared with the results for the block-diagonal MSSS preconditioner in Tables 5.1–5.3, the global MSSS preconditioner reduces the number of iterations significantly. Even though more time is spent in computing the global MSSS preconditioner for the same group of numerical experiment, the time to iteratively solve the preconditioned system is much reduced due to the fact that fewer iterations are needed. Moreover, the total computation time for the global MSSS preconditioner is less than that for the block MSSS preconditioner.

REMARK 5.2. Since there is no efficient model order reduction to reduce the 2-level semiseparable order, the 2-level semiseparable order continues growing before k_r is reached. It is shown in Tables 5.4–5.6, when k_r changes from 3 to 4 for $h = 2^{-6}$, the time to compute the global MSSS preconditioner increases dramatically. This is due to the fact that when k_r changes from 3 to 4, the 2-level semiseparable order is not bounded by a small number, but by a moderate constant. However, the computational complexity increases only slightly more than linear when h changes from 2^{-5} to 2^{-6} for $k_r = 4$. Meanwhile, the global MSSS preconditioner already gives satisfactory performance by choosing $k_r = 3$ for $h = 2^{-6}$.

6. Conclusions. In this paper, we have studied the multilevel sequentially semiseparable (MSSS) preconditioners for saddle-point systems that arise from the PDE-constrained optimization problems. By exploiting the MSSS structure of the blocks of the saddle-point system, we are able to construct the preconditioners and solve the preconditioned system in linear computational complexity for 2D problems and almost linear computational complexity for 3D problems. To reduce the computational complexity of computing the preconditioners, we have proposed a new model order reduction algorithm based on the approximate balanced truncation for SSS matrices. We evaluated the performance of the new model order reduction algorithm by comparing it with the standard model order reduction algorithm (the Hankel blocks approximation). Numerical experiments illustrate that our model order reduction algorithm is computationally cheaper than the standard method. Besides, it shows that for the optimal control of 2D PDEs, the global preconditioner reduced the number of iterations significantly compared with the block preconditioners. Both preconditioners give mesh size independent convergence and have linear computational complexity. Moreover, the global MSSS preconditioner yields regularization parameter independent convergence while the block MSSS preconditioner does not have this property.

For PDE-constrained optimization problem in 3D, since efficient model order reduction algorithm for 2- or higher- level SSS matrices is still an open problem, we apply an alternative approach to bound the 2-level semiseparable order. Numerical experiments also illustrate that the global MSSS preconditioner gives virtually both mesh size and regularization parameter independent convergence while the block MSSS preconditioner just yields mesh size almost independent convergence.

The next step of this research will be focused on applying this preconditioning technique to the optimal control of the Navier-Stokes equation. This has a wide range of applications such as control a wind farm to optimize the output power.

Acknowledgments. The authors would like to thank the anonymous referees who helped to improve the quality of this paper.
